Data Structures Using C, 2e

Reema Thareja

Chapter 5

Structures and Unions

Introduction

- Structure is a user-defined data type that can store related information (even of different data types) together.

- A structure is declared using the keyword struct followed by a structure name.

- All the variables of a structure are declared within the structure.

- A structure type is defined by using the following syntax:

```
struct struct-name
  {    data_type var-name;
       data_type var-name;
       …
  };
```

Introduction

```
struct student
{   int r_no;
    char name[20];
};
```

- The structure definition does not allocate any memory.

- It just gives a template that conveys to the compiler how the structure is laid out in memory and gives details of the members.

- Memory is allocated for the structure when we declare a variable of the structure.

- For example, we can define a variable of student by writing
    ```
    struct student stud1;
    ```

Typedef Declaration

- When we precede a struct name with typedef keyword, then the struct becomes a new type.

- For example, consider the following declaration:

```
typedef struct student
{
    int r_no;
    char name[20];
};
```

- Now we can straightaway declare variables of this new data type as we declare variables of type int, float, char, double, etc.
- To declare a variable of structure student, we will just write:
    student stud1;

Initializing Structures

- Initializing a structure means assigning some constants to the members of the structure.

- When the user does not explicitly initializes the structure then C automatically does that.

- For int and float members, the values are initialized to zero and char and string members are initialized to '\0' by default.

- The initializers are enclosed in braces and are separated by commas.

- Note that initializers should match their corresponding types in the structure definition.

Initializing Structures

- The general syntax to initialize a structure variable is given as follows:

struct struct_name

{

 data_type member_name 1;

 data_type member_name 2;

 data_type member_name 3;

....

}struct_var= {constant1, constant2, constant3, ...};

Accessing the Members of a Structure

- Each member of a structure can be used just like a normal variable, but its name will be a bit longer.

- A structure member variable is generally accessed using a '.' (dot operator).

- The syntax of accessing a member of a structure is:

  struct_var.member_name

- For example, to assign value to the individual data members of the structure variable stud1, we may write:

  stud1.r_no = 01;

Accessing the Members of a Structure

- We can assign a structure to another structure of the same type.

- For example, if we have two structure variables stud1 and stud2

  of type struct student

  struct student stud1 = {01, "Rahul", "BCA", 45000};

  struct student stud2;

- Then to assign one structure variable to another, we will write:

  stud2 = stud1;

Nested Structures

- A structure can be placed within another structure.

- Such a structure that contains another structure as its member is called a nested structure.

```
typedef struct
{ char first_name[20];
  char mid_name[20];
  char last_name[20];
} NAME;
```

```
typedef struct
{ int dd;
  int mm;
  int yy;
}DATE;
```

```
typedef struct
{  int r_no;
   NAME name;
   DATE  DOB;
}student;
```

```
To assign values to the structure fields, we will write:
struct student stud1;
stud1.name.first_name = "Janak";
stud1.DOB.dd = 15;
stud1.DOB.mm = 03;
stud1.DOB.yy= 1990;
```

Arrays of Structures

- The general syntax for declaring an array of structure can be given as:

  struct struct_name struct_var[index];

  struct student stud[30];

- Now, to assign values to the ith student of the class, we will write:

  stud[i].r_no = 09;

  stud[i].name = "RASHI";

  stud[i].course = "MCA";

  stud[i].fees = 60000;

Passing Individual Structure Members to a Function

- To pass any individual member of the structure to a function we must use the direct selection operator to refer to the individual members for the actual parameters.

- The called program does not know if the two variables are ordinary variables or structure members.

typedef struct

{   int x;

    int y;

}POINT;

POINT p1={2,3};

display(p1.x, p1.y); //passing members of p1 to function display()

Passing a Structure to a Function

- When a structure is passed as an argument, it is passed using call by value method. That is a copy of each member of the structure is made.

- The general syntax for passing a structure to a function and returning a structure can be given as:

  struct struct_name func_name(struct struct_name struct_var);

```
typedef struct
{   int x;
    int y;
}POINT;
POINT p1={2,3};
display(p1); //passing entire structure p1 to function display()
```

Passing Structures through Pointers

- C allows to create a pointer to a structure.
- Like in other cases, a pointer to a structure is never itself a structure, but merely a variable that holds the address of a structure.
- The syntax to declare a pointer to a structure can be given as:

```
struct struct_name
{
    data_type member_name1;
    data_type member_name2;
    ...................................
}*ptr;
OR
struct struct_name *ptr;
```

Passing Structures through Pointers

- For our student structure we can declare a pointer variable by writing:

  struct student *ptr_stud, stud;

- The next step is to assign the address of stud to the pointer using the address operator (&). So to assign the address, we will write:

  ptr_stud = &stud;

- To access the members of the structure, one way is to write:

  (*ptr_stud).roll_no;

- An alternative to the above statement can be used by using 'pointing-to' operator (->):

  ptr_stud->roll_no = 01;

Self-referential Structures

- Self-referential structures are those structures that contain a reference to data of its same type.

- That is, a self-referential structure contains a pointer to a data that is of the same type as that of the structure.

```
struct node
{  int val;
     struct node *next;
};
```

- Here the structure node contains two types of data: an integer *val* and *next* that is a pointer to a node. You must be wondering why do we need such a structure? Actually, self-referential structure is the foundation of other data structures.

Unions

- Similar to structures, a union is a collection of variables of different data types.
- The difference between a structure and a union is that in unions, information can be stored in one field at any one time.
- Unions are used to save memory. They are useful for applications
  that involve multiple members, where values need not be assigned to all the members at any one time.
- The syntax for union declaration can be given as :
 union union-name
 {
  data_type var-name;
  data_type var-name;
  ....
 };

Initializing Unions

```c
#include <stdio.h>
typedef union POINT2
{
    int x;
    int y;
};
int main()
{
    POINT2 P2;
    P2. x = 4;
    printf("\n The x coordinate of P2 is %d", P2.x);
    P2.y = 5;
    printf("\n The y coordinate of P2 is %d", P2.y);
    return 0;
}
```

Arrays of Unions

```c
#include <stdio.h>
union POINT
{    int x, y;
};
int main()
{    int i;
    union POINT points[3];
    points[0].x = 2;    points[0].y = 3;        points[1].x = 4;
    points[1].y = 5;    points[2].x = 6;    points[2].y = 7;
    for(i=0;i<3;i++)
    printf("\n Coordinates of Point[%d] are %d and %d", i,
        points[i].x, points[i].y);
    return 0;
}
```

Unions inside Structures

```c
#include <stdio.h>
struct student
{    union
     {    char name[20];
          int roll_no;
     };
     int marks;
};
/* in main() function*/

printf("\n You can enter the name or roll number of the student");
printf("\n Do you want to enter the name? (Y or N): ");
gets(choice);
if(choice=='y' || choice=='Y')
{    printf("\n Enter the name: ");
     gets(stud.name);
}
else
{    printf("\n Enter the roll number: ");
     scanf("%d", &stud.roll_no);
}
```
